

Ch 14 Oscillations (cont.'d)

Key words: simple harmonic motion (SHM), Hooke's Law, spring constant, spring-mass, pendulum, position function, displacement from equilibrium, frequency, period.

Objective:

- I. Solve a problem that involves a **pendulum** in SHM
 - ☐ By using the same approach for a **spring-mass** in SHM
- II. Solve for the **velocity** and **acceleration** for an object in SHM
 - ☐ By solving for $x(t)$ and then finding its **derivatives**.
 - ☐ By using **Conservation of Energy**

Content Review:

- Recall: for an object in SHM, the **position function** $x(t)$ is generally given by

$$x(t) = A \cos(\omega t + \phi)$$

where the variables are

$$A = \text{amplitude} \qquad \omega = \text{angular frequency} \qquad \phi = \text{phase shift}$$

- Taking the derivative (with respect to time) of $x(t)$ gives us the **velocity function** $v(t)$

$$v(t) = \frac{dx}{dt} =$$

- Taking the derivative of $v(t)$ gives us the **acceleration function** $a(t)$

$$a(t) = \frac{dv}{dt} =$$

- The angular frequency ω has 2 forms: spring-mass and pendulum

$$\omega_{\text{spr}} = \sqrt{\frac{k}{m}} \qquad \omega_{\text{pen}} =$$

where the variables are

$$k = \text{spring constant}, \quad m = \text{mass of object}, \quad \ell = \text{length of string}, \quad g = \text{acc. due to gravity}$$

- The **total energy** of the oscillating spring-mass system is given by

$$E_{\text{tot}} = U + K = \frac{1}{2}kx^2 + \frac{1}{2}mv^2$$

where the variables are

$$U = \text{spring potential energy} \qquad K = \text{kinetic energy}$$

Guided Practice

A pendulum has a period of 1.35 s on Earth. Suppose the same pendulum is now on Mars, where the acceleration of gravity is about 0.37 that on Earth.

- (i) Determine its period on Mars.
- (ii) How should the pendulum be modified so that its period is the same as on Earth?

Solution

- (i) $T = 2.2 \text{ s}$
- (ii) By decreasing the length of the pendulum string.

Group Activity

An object with mass 2.7 kg is executing SHM, attached to a spring with $k = 280\text{ N/m}$. When the object is 0.020 m from its equilibrium position, it is moving with a speed of 0.55 m/s .

- Determine the amplitude of the motion.
- Find the maximum speed of the object as it's oscillating.

Solution

(i) $A = 5.8 \times 10^{-2}\text{ m}$

(ii) $v_{\text{max}} = 0.59\text{ m/s}$
